MOSES LAKE WATER QUALITY DATA, 1982

Prepared by

Will Kendra

Water Quality Investigations Section  
Washington State Department of Ecology

May 1986

## INTRODUCTION

The data presented herein were collected in 1982 by Lynn Singleton and other Water Quality Investigations Section (WQIS) staff during receiving water surveys in Moses Lake. The Ecology Eastern Regional Office (ERO) asked WQIS to perform the work in order to measure lake water quality before and after cessation of discharge from the city of Moses Lake Wastewater Treatment Plant (WTP). Completion of the receiving water studies was precluded because an ongoing lake restoration program includes comprehensive post-restoration monitoring. Sampling is scheduled to begin in 1987 and should provide data concerning water quality improvements.

## BACKGROUND

Moses Lake is a 6,800 acre (2,750 ha) impoundment of Crab Creek in eastern Washington (Figure 1). Although natural in origin, a dam was installed to control water levels. Moses Lake is eutrophic, with a mean depth of 18.5 ft. (5.6 m) and a flushing rate of about twice per year. Two arms of the lake, Parker Horn and Pelican Horn, partially surround the city of Moses Lake (pop. 11,000).

The lake is fed by Crab Creek, Rocky Ford Creek, small irrigation waste-ways, and ground water inputs. Release of water occurs at two outlet structures located at the southern end of the lake. One outlet is operated by the Bureau of Reclamation, while the other is operated by the Moses Lake Irrigation District. Several smaller withdrawals from Moses Lake provide additional irrigation water to area farmers.

Research in the 1960s and 1970s by Eugene Welch (University of Washington) and others found excessive nutrient loads were encouraging nuisance algal growths in Moses Lake. Poor irrigation practices in the basin and direct discharge of Moses Lake WTP effluent to the lake were major causes of enrichment. Welch and others felt that eutrophication could be controlled by improved land-use practices in the watershed, diversion of the WTP discharge, and controlled addition of low-nutrient Columbia River dilution water to Moses Lake.

A lake restoration project was initiated in 1977. Features of the restoration program included: 1) implementation of a land-use management program to improve irrigation-land practices; 2) cessation of WTP discharges to the lake; 3) dilution of nutrient-rich Moses Lake water by adding nutrient-poor East Low Canal water to Parker Horn via Rocky Coulee Wasteway and lower Crab Creek; and 4) diversion of water from Parker Horn to Pelican Horn via a pipe and pumping facility.

The land-use management program is ongoing and scheduled to continue through 1989. Participants include the Department of Ecology, Environmental Protection Agency, Soil Conservation Service, Moses Lake Irrigation District, and City of Moses Lake. WTP discharges were terminated in March 1984 upon construction of a new WTP with land application. Diversion of East Low Canal (i.e., Columbia River) water to Parker Horn during summer months began in 1977 and pumping of lake water from Parker Horn to Pelican Horn began in 1982.

## METHODS

Water quality samples were collected at 13 stations in the immediate Moses Lake watershed (Figure 1). Sites 1-10 were located on the lake, while sites 11-13 characterized tributary inflows. Temperature, pH, conductivity, dissolved oxygen, and oxidation-reduction potential were measured in situ with a Hydrolab. Water transparency was determined using a 20-cm Secchi disk. Water samples were collected with a Kemmerer bottle, iced, kept in the dark, and transported to the Ecology Environmental Laboratory within 24 hours for analysis as per EPA (1979) and APHA et al. (1980).

Composite receiving water samples were collected by combining equal aliquots of water from all depths sampled. Chlorophyll and pheophytin composites were collected from the euphotic zone, which was taken as two times the Secchi disk depth. Each composite sample was drawn from at least three depths. Composite samples were collected from the WTP and International Titanium Incorporated (ITI) every 30 minutes over a 24-hour period.

Streamflow measurements in Crab Creek were obtained from records of USGS gage 12467000 (USGS, 1985). Flow at Rocky Ford Creek was estimated using the procedure of Buchanan and Somers (1969); current velocities required for discharge estimation were measured with a Marsh-McBirney current meter. Flows in the Rocky Coulee Wasteway were approximated by F. Jensen (Bureau of Reclamation, personal communication). WTP flows were provided by Roger Ray of Ecology's ERO.

## RESULTS

Table 1 presents water quality data from Moses Lake and several tributary streams. Table 2 presents wastewater quality data from Moses Lake WTP and ITI, which began discharging industrial wastewater to the city sewer in March 1982. A bibliography of additional studies addressing Moses Lake water quality can be found in Appendix A.

Flow patterns in 1982 were variable. Dilution water flows exceeded 700 cfs during the June 1982 survey, but ceased August 2 (F. Jensen, Bureau of Reclamation, personal communication). Diversion of lake water from Parker Horn to Pelican Horn began July 1, 1982 at a rate of 50 cfs. Pumping during that year ceased October 2. Hence, diversion of low nutrient waters to Pelican Horn was not occurring during either the June or September water quality surveys.
